

WHAT IS CLAIMED IS:

1. A method of transferring stored digital parallel data of multiple bits of data stored in a first data register from a transmitter to a receiver over a hard wired conductor comprising the steps of:

5 synchronously converting said stored digital data to a serial analog data signal in said transmitter;

transmitting said serial analog signal asynchronously over said hard wired conductor to said receiver; and

restoring said asynchronous serial analog signal to synchronous digital parallel data
10 in said receiver corresponding to the data stored in said first data register in said transmitter, including detecting both edges of the data in said asynchronous serial analog signal for conversion to parallel data bits.

2. The invention as defined in claim 1 wherein the digital parallel data is read
15 out of said first data register to at least one single bit latch.

3. The invention as defined in claim 2 wherein the data is read out from said first register in said transmitter two bits at a time, each data bit to first and second single data bit registers, and from each first and second single bit data register to a third single bit data
20 register, clocking additional two data bits to be subsequently written to said first and second one bit registers and to said third single bit data register until all bits of the data have been read from the first register.

4. The invention as defined in claim 3 wherein the bits from the third single bit register are converted to a single analog serial signal of the data.

5. The invention as defined in claim 1 wherein the data in said first register is
5 comprised of either eight or ten bits

6. The invention as defined in claim 1 wherein a clocking signal is used to convert said analog serial signal to a digital signal.

10 7. The invention as defined in claim 3 wherein said analog signal is converted in said receiver to two one-bit signals and delivered to a shift register and then stored in a second data register.

15 8. The invention as defined in claim 7 wherein said bits in the shift register are delivered synchronously from said shift register to said second data register.

9. The invention as defined in claim 1 wherein said edges are derived from multiple samples.

20 10. The invention as defined in claim 9 wherein said multiple samples are used to determine the approximate center of said resulting data bit.

11. A structure for transferring stored digital parallel data of multiple bits of data stored in a first data register, comprising a transmitter and a receiver connected by a hard wired conductor;

circuitry to synchronously convert said stored digital data to a serial analog data signal in said transmitter;

circuitry to transmit said serial analog signal asynchronously over said hard wired conductor to said receiver; and

circuitry to restore said asynchronous serial analog signal to synchronous digital parallel data in said receiver corresponding to the data stored in said first data register in said transmitter, including detecting both edges of the data in said asynchronous serial analog signal for conversion to parallel data bits.

12. The invention as defined in claim 11 including at least one single bit latch and circuitry to read the digital parallel data out of said first data register to said at least one single bit latch.

13. The invention as defined in claim 12 including first, second and third single data bit registers, and wherein the data is read out from said first register in said transmitter two bits at a time, each data bit to either said first or second single data bit registers, and then from each first and second single bit data register to said third single bit data register, clocking to clock additional two data bits to be subsequently written to said first and second

one bit registers and to said third single bit data register until all bits of the data have been read from the first register.

14. The invention as defined in claim 13 including circuitry to convert the bits
5 from the third single bit register into a single analog serial signal of the data.

15. The invention as defined in claim 11 wherein the data in said first register is
10 comprised of either eight or ten bits.

16. The invention as defined in claim 11 including a clocking signal to convert
said analog serial signal to a digital signal.

17. The invention as defined in claim 11 including a second data bit register and
15 circuitry in said receiver to convert said analog signal to two one-bit signals delivered to a
shift register, and store the converted bits in said second data register.

18. The invention as defined in claim 17 wherein said bits in the shift register are
20 delivered synchronously from said shift register to said second data register.

19. The invention as defined in claim 11 including circuitry to derive said edges
25 from multiple samples.

20. The invention as defined in claim 19 wherein said circuitry to derive said edges from said multiple samples determines the approximate center of said resulting data bit.
